Abstract
Due to the observation of a great number of patients having achrocords, when they underwent fine needle biopsies for thyroid nodules, we decided to perform a prospective study to investigate the relationship between this finding and the presence of insulin resistance (IR), since achrocords are commonly seen in hyperinsulinemic subjects. A total of 120 consecutive women, aged 18-35 yrs were studied. All subjects were also evaluated by thyroid ultrasound (US) for measuring thyroid volume and the presence of non-palpable nodules. Basal and post-prandial serum insulin was measured in all of them, as well as the Homeostasis Model Assessment (HOMA). Subjects were divided in two groups: Group A, with achrocords (n = 44) and Group B, without achrocords (n = 76). Group A showed 24 patients (54.5%) with thyroid nodules, whereas Group B only 13 subjects (17.1%); p = 0.0087. When we considered, as having high normal thyroid volume, the glands weighting more than 16 grams by US, without nodules, it was found that 8/44 cases from Group A (18.6%) and 3/76 from Group B (3.9%) fitted in such category, p = 0.0076. In patients with nodules and/or bigger thyroids, IR was observed in 36/44 (81.8%) of Group A and 14/76 (18.4%) of Group B, p = 0.0069, while the overall prevalence of IR was 0.47 in Group A and 0.05 in Group B, p = 0.00094. It is concluded that patients with achrocords have a higher prevalence of US-detected thyroid nodules and larger thyroid glands. Then, it may be beneficial to search for thyroid abnormalities in those subjects with skin tags.

Key words: thyroid nodules, insulin resistance, skin tags

Resumen
Alta prevalencia de nódulos tiroideos en pacientes con acrocordones (fibromas blandos). Posible papel de la insulino-resistencia. Debido a la alta frecuencia de acrocordones en pacientes que concurrían a nuestro servicio para realizar punciones aspirativas de nódulos tiroides, realizamos un estudio prospectivo para investigar la relación entre este hallazgo y la presencia de insulino resistencia (IR), dado que los acrocordones son frecuentemente observados en pacientes hiperinsulinémicos. Se incluyeron 120 pacientes consecutivas, con edades entre 18 y 35 años. Todas fueron evaluadas con una ecografía tiroidea para determinar su volumen y la presencia de nódulos no palpables. Se midió insulinaemia basal y post prandial, así como el índice Homeostasis Model Assessment (HOMA). Las pacientes se dividieron en 2 grupos: Grupo A, con acrocordones (n = 44) y Grupo B, sin acrocordones (n = 76). En el Grupo A se encontraron 24 (54.5%) con nódulos tiroideos, mientras que el Grupo B, sólo 13 (17.1%); p = 0.0087. Cuando consideramos la presencia de una glándula tiroidea de tamaño elevado pero dentro de los límites normales, medida por ecografía (peso mayor a 16 gramos sin nódulos), encontramos que 8/44 casos del Grupo A (18.6%) y 3/76 del Grupo B (3.9%) entraron en esta categoría, p = 0.0076. En aquellas pacientes con nódulos tiroides o glándula tiroides de mayor tamaño, observamos IR en 36/44 (81.8%) del Grupo A y en 14/76 (18.4%) del Grupo B, p = 0.0069, mientras que la prevalencia total de IR fue del 0.47 en el Grupo A y del 0.05 en el Grupo B, p = 0.00094. En conclusión, las pacientes con acrocordones tuvieron mayor prevalencia de nódulos tiroides detectados por ecografía, glándula tiroidea de mayor tamaño y mayor proporción de insulino resistencia.

Palabras clave: nódulos tiroideos, insulino resistencia, acrocordones

Skin tags (achrocords) are skin-colored, pedunculated tumors with a smooth surface. Histologically they are composed by loose collagen fibers and dilated capillaries. The association of acanthosis nigricans, skin tags, diabetes mellitus, insulin resistance (IR), and obesity in adolescents and young adults represents a well defined association. The endocrine origin of this condition is beyond doubt. Insulin and insulin-like growth factor-1, and their receptors on keratinocytes are obviously involved in the complex regulations leading to the peculiar epidermal hyperplasia. Control of obesity contributes largely to reverse the whole process, essentially by reducing both insulin resistance and compensatory hyperinsulinemia, although skin tags usually remains without change after IR normalization.
Due to the observation of a great number of patients having skin tags, when they underwent fine needle biopsies for thyroid nodules in our Clinic, we decided to perform a prospective study to investigate the relationship between this finding and the presence of IR, since achrocordons are commonly seen in hyperinsulinemic subjects.

**Materials and Methods**

One hundred and twenty consecutively by assisted women, mean age 24.2 ± 7 years, range 18-35 years, living in an iodine sufficient area, who attended our Clinic for endocrinological evaluation, were included in the study. To be incorporated in this protocol, patients had to have: 1) normal thyroid function, as determined by the measurements of T3, T4, and TSH, 2) negative titers of antithyroid antibodies (TPO-Ab), 3) no past history of thyroid abnormalities, and 4) no past history of any thyroid and/or having received homeopathic medication.

Subjects were divided into two groups as follows: Group A, with achrocordons (n=44) and Group B, without achrocordons (n=76).

All subjects gave written voluntary consent to participate in the study. Procedures were applied in agreement with the ethical guidelines of our Institutions.

Body weights (kg) and heights (cm) were measured without shoes and/or cap. Body mass index (BMI) was expressed as weight per height square (kg/m²). Obesity was defined as BMI higher than 30.

All blood samples were taken between 8:00 and 9:00 a.m. after 12 hours of fasting period. After collection, serum samples were stored at –20 ºC until assayed.

Basal and 2-hour postprandial glycemia and insulinemia were monitored. The post prandial samples were obtained 2 h after a standard mixed meal intake, as previously described. Breakfast included proteins, carbohydrates and fats.

Insulin was determined as previously described. Hyperinsulinemia was considered when basal levels were > 20 uIU/ml or > 60 uIU/ml in the post prandial state.

Glycemia was determined as previously described. Homeostasis Model Assessment index (HOMA) was calculated from insulin and glycemia values as previously described. A high HOMA index (> 2.5) generally reflects insulin resistance.

The thyroid hormones, thyrotrophin (TSH) and antithyroid peroxidase antibodies (TPO-Ab) were measured by electrochemiluminescent technology (ECL) with an automatic analyzer (Roche Diagnostics Elecsys 2010 Immunoassay System, Mannheim, Germany).

Thyroid ultrasound scanning (US) was performed in all patients by using a 7.5 MHz linear transducer. Thyroid volume (TV) was calculated by the elliptical shape volume formula (0.479 x length x width x height) for each lobe as previously described. We considered as thyroid nodules, all the US nodular lesions greater than 3 mm.

Results are expressed as means ± SD. Between-group comparisons were made using Student’s t-test for independent samples of cases of normal distribution. The Wilkoxon rank-sum test was used for independent samples of cases of abnormal distribution. The Chi-square test was used for nominal variables. The level of significance was set at 0.05.

**Results**

In Group A, 24 (54.5%) patients presented thyroid nodules, whereas Group B only 13 (17.1%) subjects, p = 0.0087 (Table 1).

When we considered, as having high normal thyroid volume, the glands weighting more than 16 grams by ultrasonography (US), excluding those which had thyroid nodules, it was found that 8 /44 (18.6%) cases from Group A and 3/76 (3.9%) from Group B fitted in such category, with an statistically significant difference, p = 0.0076 (Table 1). Taking together those patients with thyroid nodules and/or bigger thyroid glands, IR was observed in 36/44 (82%) subjects of Group A and in 14/76 (18%) subjects of Group B, p = 0.0069 while the overall prevalence of IR was 0.47 in Group A and 0.05 in Group B, p = 0.00094 (Table 1).

**Discussion**

Skin tags are known to be more common after the age of 40 years. In this series, the frequency of achrocordons was 37%, higher than the prevalence of skin tags in the general population which is estimated around 20 to 25%.

There have been a few reports in the literature showing that the presence of skin tags is associated with diabetes mellitus. It has also been reported that these lesions might be associated with insulin resistance, with...
an atherogenic lipid profile and a lot of discussion has been made about if achrocordons constitute a marker for colon polyps.

On the other side, we have recently shown that those subjects with IR have a higher prevalence of greater thyroid volumes and thyroid nodules. We believe that the higher circulating levels of insulin might be causing increased thyroid proliferation. The clinical manifestations would be the larger thyroid volume and the formation of nodules.

Insulin resistance is a characteristic feature of most patients with simple obesity, polycystic ovarian syndrome, and impaired glucose tolerance, as well as other disorders. In a recent publication, it has been reported that increased BMI is associated with increased risk of common and less common malignancies. These epidemiological observations should inform the exploration of biological mechanisms that link obesity with cancer, and probably insulin resistance have much to do with this, considering that it is a growth factor which can act systemically.

In our study, we have observed that patients with achrocordons have a higher prevalence of US-detected thyroid nodules and larger thyroid glands. According to these results, we recommend that in those patients with achrocordons, it may be beneficial to search for thyroid abnormalities. On the other side, insulin resistance will usually be present in patients with skin tags, as it was observed in our series. Therefore, we suggest that IR would be directly involved in thyroid proliferation and the development of achrocordons, as well. For this reason, in all subjects with achrocordons the possibility of the presence of IR and thyroid nodules is encouraged to be investigated.
